

IGA as a Record — Worked Example

A demonstration of how the Pikes Peak Regional Civic Records Platform Intergovernmental Agreement is itself represented as a Record on the platform it authorizes.

This is the self-referential loop: the legal document that brings the platform into existence is one of the public records the platform serves. Same schema, same provenance, same audit log, same citizen visibility as every other record.

The example uses a hypothetical IGA between three real Colorado jurisdictions (City of Colorado Springs, El Paso County, PPRBD). The specific dates, dollar amounts, and signatures are illustrative only — no such IGA exists in reality.

The IGA Record

What's interesting about this representation

A few things worth pulling out, because they show the schema doing work that wouldn't be possible without the multi-jurisdictional infrastructure.

The IGA's governing jurisdiction is the IGA's own governing board

Notice `governing_jurisdiction_id:`
`"juris_iga_governing_board_pikes_peak_civic_records"`.

The IGA isn't governed by any single signatory party. It's governed by the Board the IGA itself creates. This is the bootstrapping problem solved cleanly — the document creates the body that has authority over it. The Board is itself a `JurisdictionalAuthority` in the schema, with its own signatories and its own scoped authorities, and its existence flows from this very IGA.

This means amendments, withdrawals, and other modifications to the IGA are signed actions performed by Board-authorized actors, not by any individual party acting alone. No single party can quietly modify the agreement.

The audit log tells the IGA's complete biography

The `signed_actions` array on the IGA Record traces the document's entire life: created, opened for public comment, comments closed, executed, filed with DOLA, marked active. Each is a separate signed action with its own actor, timestamp, and reason.

Anyone reading the IGA Record can see exactly when it was drafted, when public comment happened, who voted on it in each governing body, when it was filed, and when it became operationally active. There's no separate "process tracking" system — the schema's audit log handles it.

The connected records express the document's structural role

Three connected records: the Schema (which the IGA incorporates by reference), the Governing Board (which the IGA creates), and the Operator Designation (which the IGA references through Appendix B).

These three relationships make the IGA's role in the platform's architecture explicit and queryable. Anyone studying the platform's governance can navigate from the IGA to the Schema, to the Board, to the Operator, in one click each.

Public comments are themselves a document on the record

The `doc_iga_public_comments_received` document captures the public input received during comment period as a first-class part of the record. The 47 comments aren't lost in a separate inbox — they're attached to the IGA, attributed (or pseudonymized as appropriate), and visible as part of the historical record.

This is the kind of structural change to public processes the platform enables. The traditional way is "comments come in, staff considers them, final document published, comments disappear." The schema-aware way is "comments come in, attached to the record, comment period ends, document finalized, the entire dialogue remains visible."

The IGA and the Schema are mutually referential

Article 11 of the IGA incorporates the Schema by reference. The Schema provides the `intergovernmental_agreement` record type that represents the IGA. Each defines the other.

This isn't circular in a bad way — it's the same pattern as a constitution that establishes the institutions that interpret and amend it. The legal document defines the technical specification's authority; the technical specification provides the structure for the legal document's representation. Together they're a complete unit.

The completeness counter is at 100%

`manifest_completeness.completeness_percent: 100`.

Unlike the C-12102 contract example where the manifest was at 33% (many documents pending or denied), the IGA Record is complete. Every document the schema expects for an IGA — the executed agreement, all appendices, the approving resolutions from each party, the DOLA filing receipt, the public comments — is present and available.

This is itself a kind of accountability signal. A platform's most foundational record (its own governing IGA) being at 100% completeness demonstrates that the platform's transparency principles apply to its own governance, not just to the records it publishes.

If the IGA Record were missing one of the resolutions or the public comments, the completeness counter would surface that gap. Anyone could see "the platform's IGA is at 91% completeness; one signatory party's approving resolution is missing" and could file a CORA request to obtain it. The platform polices its own transparency.

A note on what this demonstrates more broadly

This document is the smallest possible demonstration of the self-referential loop that makes this approach genuinely different from existing civic records systems.

Every existing records platform has *its own* records — the platform's contracts, its policies, its internal documentation — separate from *the records it manages*. Those internal records are typically opaque, governed by the vendor or operator's own policies, and not subject to the same public-records standards as the records being managed.

The platform described by this schema collapses that distinction. The IGA, the Operator Designation, the Schema itself, the Governing Board's meeting minutes — all of these are records on the platform, with the same provenance, audit log, completeness tracking, and citizen-visibility as a contract or a permit.

The platform that publishes records about government cannot itself be a black box. The schema's structure makes that consistency mandatory rather than optional.
